Personal AI Assistant
CSCE 689

Oluwasegun Oluwole

October 26, 2025

1 Objective

Write a personal AI assistant using MCP that can

- Write and send emails on your behalf (1pt)
- Read multiple PDF files and answer questions (1pt)
- Schedule meetings for you (1pt)
- Search the Internet for real-time information (1pt)
- Order pizzas for you (2pt)
- Ask you questions, e.g., for your private information or when uncertain (2pt)

2 Solution

I configured an MCP Server on Zapier using their Zapier MCP beta functionality. On this MCP server, I exposed the necessary tools for writing and sending emails, scheduling meetings, reading multiple PDF files, and answering questions. I used Gmail for emails, Google Meet for meetings, and PDF.co for PDF files. In order to search the internet for real-time information, I connect remotely to the Firecrawl MCP server. I could not find any MCP server/official API for ordering pizza so instead I created a function that utilizes playwright to automate visiting the webpage, inputting my address for ordering pizza, and adding the pizza I want to my cart.

2.1 Architecture

I utilized the OpenAI Agents framework to create the Agents that make up my personal assistant. There are the Personal Assistant Agent and the Pizza Ordering Agent. The Personal Assistant will use the provided MCP tools to help answer and fulfill any user queries. The Personal Assistant Agent interacts with the OpenAI

cloud models(if mode is not specified in Agent object, default is GPT-4.1) to answer user queries, where as the Pizza Ordering Agent utilizes a pruned version of GPT-OSS-20B running on my local machine via LMStudio. If the user query pertains to ordering pizza, the Personal Assistant Agent will delegate the task to the Pizza Ordering Agent which will then ask the user for the required (private information), write a python script, save the python script and execute the python script(the function from pizza_order_browser.py called order_pizzas) which will go to the Domino's pizza website and add the user's order to their cart.

3 Challenges/Failures

The pizza ordering functionality is limited in what the user can order as it requires the user to go to the Domino's pizza webpage and look at what is under specialty, and enter the name of one of the specialty pizzas and the quantity that they want. Furthermore, the local model sometimes does not output the correct Python code to order the pizzas, so the agent may need to be asked to order the pizza more than once or the user can manually edit the generated python code to fix the syntax errors. I suspect the issues with the python code generation have to do with how the local model I used was pruned to optimize speed and use less memory at the expense of model accuracy.

4 How to Run

a. set OPENAI_API_KEY in environment

b. start/activate virtual environment

c. pip install -r requirements.txt

d. download/load gpt-oss-20b-pruned-10.2b in LM Studio

e. Run agent

5 Future Improvements

Instead of creating python function utilizing playwright to work specifically for domino's pizza, utilize playwright MCP server so the LLM has more freedom based on the tools provided to navigate the webpages, prompt user for required information, and input required information.
